# Working with FHIR Terminology Services – From a Coder's Perspective

Joshua Wiedekopf, M.Sc.

IT Center for Clinical Research | Institute of Medical Informatics Universität zu Lübeck | Universitätsklinikum Schleswig-Holstein

Workshop FHIR Terminology Services 2021-07-05

# What I'm Going To Talk About Today

- Interactive creation with Snapper is not always sufficient, and resources want to be consumed
- Accessing FHIR APIs is easy and powerful
- We will do the following today:
  - List resources on the server
  - Validate that a code is contained by a CodeSystem/ValueSet
  - List all codes in a CodeSystem/ValueSet for selection by the user
  - Expansion of SNOMED CT Expression Constraint Language expressions
  - Conversion of a table in a relational DB to FHIR CodeSystem & Mapping to LOINC
- Demonstration of common patterns implemented in Python
  - Some implementations also in Java/Spring Boot, for demonstrating usage patterns

#### Convention

- https://github.com/itcr-uni-luebeck/fhir-term-samples
- Python Dependencies (via python -m venv):
  - fhir.resources
  - requests
  - rich, questionary
- Java Dependencies (via Gradle):
  - ca.uhn.hapi.fhir:{hapi-fhir-structures-r4, hapi-fhir-client}:5.4.1
    - org.apache.httpcomponents:httpcomponents-client
  - org.projectlombok:lombok
  - Spring Boot 2.5.2
- Cave: You may need to URL-encode request parameters!

## **Authentication**

- Provide DFN certificate for every request (unless on IP allow list)
- "Workaround" Use your reverse proxy to handle authentication transparently!
  - also great for adding a cache like Varnish in front of the SSL termination for speed and reliability...

```
location /onto/ {
                       https://terminology-highmed.medic.medfak.uni-koeln.de:443/;
    proxy_pass
                                    /etc/pki/ontoserver/certs/cert-with-chain.pem;
    proxy_ssl_certificate
    proxy_ssl_certificate_key
                                    /etc/pki/ontoserver/certs/private.pem;
    proxy_ssl_protocols
                                    TLSv1.2 TLSv1.3;
    proxy_ssl_ciphers
                                    HIGH: !aNULL: !MD5;
    proxy_ssl_trusted_certificate
                                    /etc/pki/ontoserver/chain/chain.pem;
    proxy_ssl_verify
                                    on;
    proxy_ssl_verify_depth
                                    5;
```

# **Authentication in Python**

```
import requests
from fhir.resources.capabilitystatement import CapabilityStatement
endpoint = "https://terminology-highmed.medic.medfak.uni-koeln.de/fhir/metadata"
sess = requests.Session() # create a persistent session/connection
cert_file = "../joshua_dfn.pem" # contains both certificate and private key
#cert_file = ("../joshua_dfn.crt", "../joshua_dfn.key") # two files for public/private key
sess.cert = cert_file # applies to all request initiated from the session
response = sess.get(endpoint) # issue the actual request (without preparing it)
conformance = CapabilityStatement(**response.json()) # parse as FHIR
software = conformance.software # access structure of FHIR resource
print(f"{software.name} version {software.version}")
###############
# Ontoserver® version 6.2.3
##############
```

# **Python: Key Material**

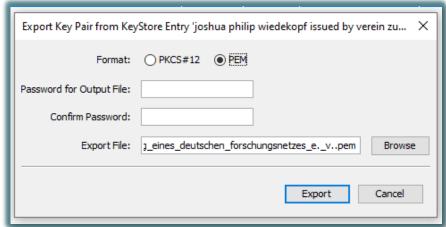

- Python expects OpenSSL/PEM format for key material
- Convert from PKCS#12 using OpenSSL

openssl pkcs12 -in path.p12 -out cert\_with\_key.pem -nodes

Or use <u>Keystore Explorer</u>

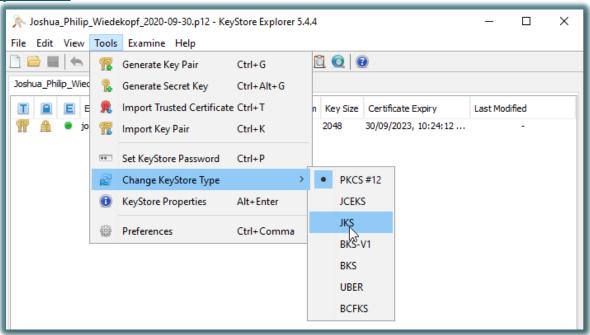

#### **Authentication in Java**

```
URL keystorePath = ClassLoader.getSystemResource("keystore.jks"); //get keystore resource
char[] password = "pw".toCharArray(); //password of keystore and key (could as well be different)
try {
  SSLContext sslContext = SSLContexts.custom() //load key material, trust comes from system default
    .loadKeyMaterial(keystorePath, password, password).build();
 CloseableHttpClient client = HttpClients.custom().setSSLContext(sslContext).build();
  final FhirContext fhirContext = FhirContext.forR4(); //do this exactly once during app lifecycle
  final IRestfulClientFactory restfulClientFactory = fhirContext.getRestfulClientFactory();
  restfulClientFactory.setHttpClient(client); //all new clients will use custom HTTP Client
  final String serverBase = "https://terminology-highmed.medic.medfak.uni-koeln.de/fhir";
  IGenericClient fhirClient = fhirContext.newRestfulGenericClient(serverBase);
  CapabilityStatement capabilities = fhirClient.capabilities().ofType(CapabilityStatement.class)
    .execute(); //query the metadata and parse as CapabilityStatement (could be subclass)
  System.out.printf("%s %s%n", capabilities.getSoftware().getName(),
    capabilities.getSoftware().getVersion()); //access the nodes of the parsed capability statement
} catch (Exception e) { //... }
                                                                              Ontoserver 6.2.3
                                                                              BUILD SUCCESSFUL in 11s
```

# **Java: Key Material**

- Java works using keystores & truststores
- Using PKCS#12 is possible, or convert to JKS
  - Use <u>Keystore Explorer</u>

# **Spring Boot: Authentication – REST Template Bean**

```
@SpringBootApplication public class Application {
  @Bean @SneakyThrows public RestTemplate fhirRestTemplate(FhirSslProps fhirSslProps,
  @Value("classpath:keystore.jks") Resource keystoreResource) { //inject resource/settings
    SSLContext sslContext = SSLContexts.custom().loadKeyMaterial(keystoreResource.getURL(),
      fhirSslProps.getKeystorePassword().toCharArray(),
      fhirSslProps.getKeyPassword().toCharArray()).build(); //load material from resource
    CloseableHttpClient httpClient = HttpClients.custom().setSSLContext(sslContext).build();
    ClientHttpRequestFactory clientRequestFactory =
      new HttpComponentsClientHttpRequestFactory(httpClient); //create a new request factory
    return new RestTemplate(clientRequestFactory); //and wrap it as a template
  @Bean public FhirContext fhirContext() { return FhirContext.forR4(); } //create once, use often
  public static void main(String[] args) { SpringApplication.run(Application.class, args); }
@Data @ConfigurationProperties(prefix = "fhir.ssl") class FhirSslProps { //holder for SSL settings
  private char[] keystorePassword, keyPassword; //injected from application.yml
```

## **Spring Boot: Authentication – FHIR Service Bean**

```
@Service public class FhirService {
  private final FhirContext fhirContext;
  private final RestTemplate fhirRestTemplate;
  private final URI endpoint = URI.create(
    "https://terminology-highmed.medic.medfak.uni-koeln.de/fhir".replaceAll("/$", ""));
 @SneakyThrows public <T extends Resource> T getResourceFromPath(String path, Class<T> clazz,
Object... variables) throws HttpClientErrorException {
    String resolved = String.format("%s/%s", endpoint, path);
    ResponseEntity<String> response = fhirRestTemplate.getForEntity(resolved,
      String.class, variables);
    if (response.getStatusCode().is2xxSuccessful())
      return fhirContext.newJsonParser().parseResource(clazz, response.getBody());
    throw new HttpClientErrorException(response.getStatusCode(),
      String.format("Error requesting %s", resolved.toString()));
  //...Constructor...
```

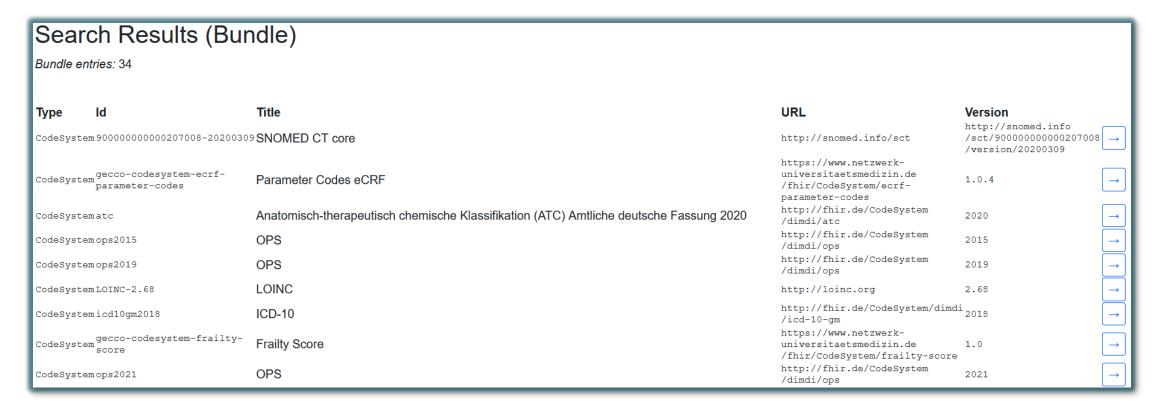

# **Spring Boot: Authentication – FHIR Service Bean**

```
@Controller @RequestMapping("/metadata")
public class MetadataDemoController {
  private final FhirService fhirService; //inject FHIR service
  private final CapabilityStatement metadata; //request the metadata once, it won't change often
  @SneakyThrows public MetadataDemoController(FhirService fhirService) {
    this.fhirService = fhirService;
    this.metadata = fhirService.getResourceFromPath("metadata", CapabilityStatement.class);
  @SneakyThrows @GetMapping("/version")
  public ModelAndView queryVersion(Map<String, Object> model) {
    model.put("data", String.format("%s %s",
      metadata.getSoftware().getName(), metadata.getSoftware().getVersion()));
      //write data to view model
                                                                             localhost:8080/metadata/version
    return new ModelAndView("simpleData", model);
                                                            Ontoserver® 6.2.3
```

## **List Resources**

https://endpoint.de/fhir/{CodeSystem, ValueSet, ConceptMap}

## **Helper API**

```
from requests import Session
class FhirApi:
    def __init__(self, cert_file: str = "dfn.pem", endpoint: str = "https://terminology-..."):
        self.session = Session(); self.cert_file = cert_file; self.session.cert = self.cert_file
        self.endpoint = endpoint.rstrip("/") # remove slash at end to make sure that joining the path works
    def build_url(self, path: str) -> str:
        return self.endpoint + "/" + path.lstrip("/") # remove slash at beginning also
    def request_and_parse_fhir(self, path: str, resource):
        request_url = self.build_url(path)
        response = self.session.get(request_url)
        if response.status_code >= 200 and response.status_code < 300:</pre>
            try: # very simplistic error handling
                return resource(**response.json()) # parse with given class
            except Exception as e:
                raise ValueError(f"Parsing the response was not possible") from e
        else:
            raise SystemError(f"Error requesting from {request_url}, status code {response.status_code}")
```

File: python/get\_session.py

#### List resources

```
from get_session import FhirApi
from fhir.resources.bundle import Bundle
fhir_api = FhirApi() # use default settings
bundle : Bundle = fhir_api.request_and_parse_fhir("CodeSystem", Bundle)
# request a bundle of Code Systems
resources = [r.resource for r in bundle.entry] # we only care about the entries
resources.sort(key=lambda r: (r.name if r.title is None else r.title, r.version))
# order by name/title and version
for r in resources:
   name = r.name if r.title is None else r.title
    print(f" - '{name}' ({r.url}, version {r.version})")
# - 'AdministrativeGender' (http://hl7.org/fhir/administrative-gender, version 4.0.1)
# - 'Anatomisch-therapeutisch chemische Klassifikation (ATC) Amtliche deutsche Fassung
    2020'(http://fhir.de/CodeSystem/dimdi/atc, version 2020)
```

File: python/list\_resources.py

? Code: C09A
The code 'C09A' ('ACE-HEMMER, REIN') belongs to the ValueSet.
```

```
? ValueSet to use? BirthSex (https://www.netzwerk-universitaetsmedizin.de/fh
ir/ValueSet/birth-sex v1.0)
? Code System of the code? http://hl7.org/fhir/administrative-gender version
None
? Code: QUZ
The specified code 'QUZ' is not known to belong to the specified code system
'http://hl7.org/fhir/administrative-gender'
```

# **Query Codes from ValueSets with Filter**

- Querying the entire CodeSystem is generally not advised
- Use the expansion of the relevant ValueSet instead
- http://endpoint.de/fhir/ValueSet/\$expand
   ?url=http://hl7.org/fhir/ValueSet/dicom-dcim&version=01
   &filter=frame
- CodeSystems (often) have canonical URL assigned to implicit ValueSet with all concepts that can be used for \$expand

## **Code Validation within CodeSystems**

```
# request the list of code systems with valueSet set, and ValueSets, from API
# prompt user for CS/VS, and for optional filter
request_path = f"ValueSet/$expand?version={version}&url={url}"
if filter.strip():
  request_path += f"&filter={filter}"
valueset: ValueSet = fhir_api.request_and_parse_fhir(request_path, ValueSet)
# prompt user for selection of a code from (filtered) list
lookup_path = f"CodeSystem/$lookup?code={sel_code}&system={sel_url}"
# lookup details of the selected concept
lookup: Parameters = fhir_api.request_and_parse_fhir(request_path, Parameters)
def print_parameter_value(param_name: str, parameters: Parameters, print_name = None):
  # rather easy print routine
print_parameter_value("name", lookup, "CodeSystem Name")
print_parameter_value("version", lookup, "CodeSystem Version")
print_parameter_value("display", lookup, "Code Display")
print_parameter_value("designation", lookup, "Code Designation")
```

#### **Conversion to FHIR Resources**

- Create CodeSystem for local codes
- ValueSet for mapped LOINC codes
  - Validation of all concepts, since they might be entered-in-error
- ConceptMap for mapping from Local → LOINC

File: legacydb.sqlite3 25

## **Conversion to FHIR Resources – Step 1: Query Database**

import sqlite3

```
# select everything from the db
sql = "SELECT code, display, unit, loinc FROM lab_codes;"
sqlconn = sqlite3.connect("../legacydb.sqlite3")
sqlconn.row_factory = sqlite3.Row # access rows using Row interface, instead of tuples
cur = sqlconn.cursor()
# list the available concepts from the DB as list of dict
# loads everything into memory. Propably not a good idea for all real applications...
defined_concepts : List[Dict[str, str]] = []
for row in cur.execute(sql):
    defined_concepts.append(dict(zip(row.keys(), row)))
    # this produces a list of dicts with the column names as keys
```

# **Conversion to FHIR Resources – Step 2: Define Attributes**

```
# query for attributes of the FHIR CodeSystem

cs_answers = questionary.form(
    url = questionary.text("Canonical URL of the CodeSystem?"),
    valueSet = questionary.text("Canonical URL of the implicit ValueSet?"),
    version = questionary.text("Version?", validate=NotEmptyValidator) # ...).ask()

cs_answers.update({
    "id": cs_answers["name"], # the name is used as the ID for simplicity
    "content": "complete" # content will generally be complete for simple CS
})

code_system = CodeSystem(**cs_answers)

code_system.property = [CodeSystemProperty(**{"code": "unit", "type": "string"})]
```

# Conversion to FHIR Resources – Step 3: Create Concepts

```
code_system.concept = [
   CodeSystemConcept(**{
        "code": c["code"],
        "display": c["display"],
        "property": [
            CodeSystemConceptProperty(**{
                "code": "unit",
                "valueString": c["unit"]
                })
        }) for c in defined_concepts
```

# Conversion to FHIR Resources – Step 4: Enumerate & Validate LOINC

```
# create valueset from user answers, as with CodeSystem
valueset_concepts = []
loinc_concepts = []
for concept in defined_concepts:
    loinc = concept["loinc"]
   if loinc is None:
        # loinc is nullable in DB
        continue
    valid, display = fhir_api.lookup_code_display("http://loinc.org", loinc)
    # requests http://endpoint.de/fhir/CodeSystem/$validate-code
    # ?system=http://loinc.org&code={code}
    if not valid:
        # skip the concepts that are invalid
        continue
    loinc_concepts.append({"code": loinc, "display": display})
```

# **Conversion to FHIR Resources – Step 5: Create VS Compose**

```
valueset.compose = ValueSetCompose(**{
    "include": [{
        "system": "http://loinc.org",
        "concept": [ValueSetComposeIncludeConcept(**c) for c in loinc_concepts]
    }]
})
# creating the ConceptMap is more of the same patterns!
```
